12

13

14 **Abstract** Atmospheric electricity measurements were made at several sites close to Garmisch-Partenkirchen
15 during four decades from 1950 to 1990 by Dr Reinhold Reiter, together with other environmental measurements.
16 The quantities determined include the atmospheric potential gradient, the vertical current and the ion
17 concentrations, and observations made at the Mount Wank site (1780 m, 47° 30' N, 11° 09' E) from 1st August
18 1972 to 31st December 1983 are available in digital form.

19

20 Keywords: Potential Gradient, conduction current; global circuit;

21

22 **1. Introduction**

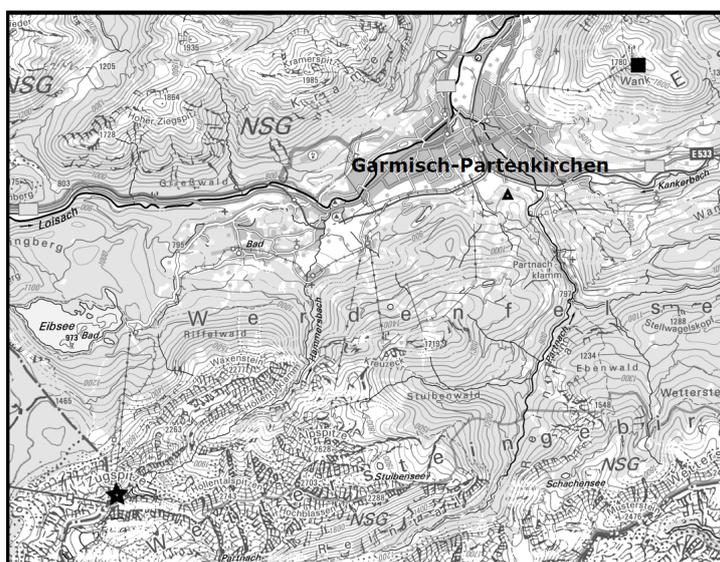

23 Motivated by his interest in the influence of atmospheric electric processes on humans,
24 Reinhold Reiter (1920-1998) started atmospheric electricity measurements in the early 1950s.
25 Past measurements of atmospheric electricity are increasingly studied internationally (Aplin,
26 2020), because of widening interest in the global atmospheric electric circuit and its relevance
27 to climate (e.g. Nicoll et al., 2019). Data obtained in clean air conditions are of particular
28 importance, such as from mountain sites. The atmospheric electrical quantities obtained by
29 Reiter within a sustained campaign of environmental measurements frequently fulfilled the
30 clean air requirements.

31

32 Retier began with various measuring sites in Munich and southern Bavaria, probably to allow
33 intercomparisons. Later, he concentrated on measurements undertaken at Garmisch-
34 Partenkirchen, on the nearby Wank and Zugspitze mountains and onboard an instrumented
35 passenger cable car moving regularly between the Eibsee and the Zugspitze summit. (The
36 locations of these sites are shown in Fig. 1).

37

38

39 Figure 1: Area around Garmisch-Partenkirchen (southern Bavaria, Germany) with the
40 observational sites marked: Wank (square, upper right), Central Institute (triangle) and
41 Zugspitze (star, lower left). The cable car runs almost directly north from the Zugspitze
42 summit to the right hand shore of lake Eibsee (map adapted from Digitale Topographische
43 Karte 1 : 100.000 (c) Bayerische Vermessungsverwaltung 2022, thanks to Martin Fasbender).

44

45 To undertake this, Reiter founded a privately-funded research institute, the *Physikalisch-*
46 *bioklimatische Forschungsstelle in Garmisch-Partenkirchen* which was incorporated as the
47 *Fraunhofer-Institut für Atmosphärische Umweltforschung (IFU)* in the Fraunhofer Society in
48 1962. He led this institute as its director until his retirement in 1985. In 2002 this institute
49 became part of the *Institut für Meteorologie und Klimaforschung Atmosphärische*
50 *Umweltforschung (IMK-IFU)*, and Campus Alpin of the *Karlsruher Institut für Technologie*
51 (KIT).

52

53 Reinhold Reiter passed away on 24 September 1998 and a detailed memorial article was
54 published by Weihe (1999). It is understood that some possessions were bequeathed to Ettal
55 Abbey, a Benedictine monastery in Bavaria.

56 **2. Measurement locations**

57 Reiter's principal scientific motivations were to investigate biometeorological responses to
58 atmospheric variables such as the concentrations of small ions, and to study short-term solar-
59 terrestrial influences on the global circuit. This may be reflected in the choice of mountain sites
60 for the measurements, which brought the possibility of low pollution conditions and least local
61 disturbances.

62

63 The Garmisch-Partenkirchen measurements were obtained at permanent sites on the Zugspitze
64 (2964 m altitude) and Wank (1780 m) mountains, and at an additional site known as the Central
65 Research Institute, on the valley floor (740 m). A novel feature was the use of the cable car
66 connecting the Zugspitze and a ground station close to lake Eibsee, instrumented to carry
67 sensors in a regular path, sometimes passing repeatedly through fog and cloud layers. Vertical
68 profiles of ozone were obtained using this approach (Reiter, 1991).

69 **3. Apparatus**

70 Customised instruments and systems were devised for the atmospheric electrical
71 measurements. A primary quantity studied was the vertical potential gradient (PG). On Wank,
72 as well as on the cable car, a radioactive collector probe was used, connected to a high
73 impedance electrometer amplifier. The PG sensing probe was heated, and its physical
74 construction refined during a long period of operation in mountain conditions, especially
75 precipitation. The atmospheric conductivity was measured with an aspirated Gerdien
76 condenser. A further measurement of the PG was made using an electrostatic field mill, and
77 the air-earth current with a wire antenna. A special device was developed for measuring the
78 space charge and, simultaneously, the natural radioactivity in the air. Beyond the usual fair
79 weather measurements, the precipitation current density was obtained with an electric rain
80 gauge. All these instruments and corresponding results are described in papers (Reiter, 1977a,
81 b), and Reiter's textbook (Reiter, 1992).

82 **4. Data recovery**

83 Some of the measurements from the Bavarian Alps have previously been made available on a
84 CDROM, which was originally distributed through the collaborative network provided by the
85 SPECIAL scientific community (Rycroft and Füllekrug, 2004). These data values were
86 retrieved from magnetic tapes in summer 2000, with the help of one of Reiter's collaborators.
87 They provide hourly values from the Wank site (1780m, 47°30'N, 11°09'E), and span 1st
88 August 1972 to 31st December 1983. The wide range of quantities recorded is summarised in
89 Table 1, with the atmospheric electricity quantities identified.

90

91 **Table 1. Quantities recorded on Mount Wank (1972-1983)**

<i>Description of measured quantity</i>	<i>Symbol used in dataset</i>
Meteorological and Environmental	
air temperature	T
relative humidity	RF
water vapor partial pressure	E
specific humidity unit	SF
potential temperature	TH
equivalent potential temperature	THE
wind speed	WG
wind direction	WR
Sunshine duration	SD
Global solar irradiance	GS
Sky radiation	HS
UV intensity	UV
Atmospheric Electrical	
Electric field	F
Zero crossing of F	DU
Vertical current	I
Positive ion concentration	N+
Negative ion concentration	N-

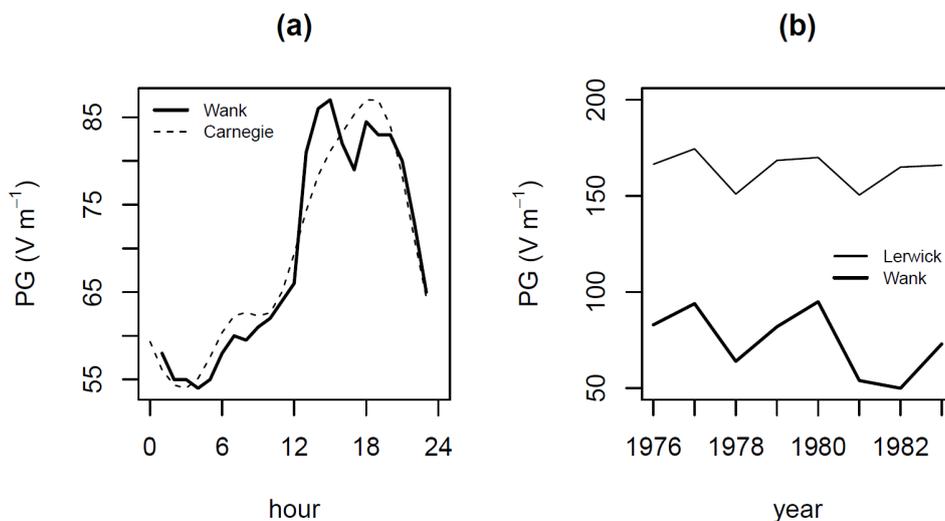

Total ion concentration	SN
Positive ion conductivity	L+
Negative ion conductivity	L-
Total ion conductivity	SL
Number concentration of condensation nuclei	K1, K2, K3

92

93 **5. Discussion**

94 The PG measurements obtained were over a sufficiently extended period to provide statistical
 95 support for suspected solar effects on the lower atmosphere (Reiter, 1977b), which was a major
 96 topic of research interest in the 1970s (e.g. Olson, 1971). Figure 2 shows examples from the
 97 PG measurements, using data from the month of December only. In fig 2(a), the daily variation
 98 is shown, which follows the global circuit’s “Carnegie curve” variation. In fig 2(b), there is
 99 some consistency evident with variations in annual PG measurements made in Shetland
 100 (Harrison and Riddick, 2022), again suggestive of global circuit influences.

101

102 Figure 2. Examples of Potential Gradient (PG) data from the Wank site. (a) Hourly median
 103 PG using December-only values, 1976-1983 (solid line), overplotted on (relative) Carnegie
 104 curve for November-December-January. (b) Annual December values for Lerwick (thin line)
 105 and Wank (thick line), from Harrison (2004).

106 **6. Conclusions**

107 Atmospheric electricity and other environmental measurements were made in the Bavarian
108 Alps over a long period, from which a series of hourly measurements for much of the 1970s
109 available digitally. In the PG data, the presence of global and solar-terrestrial signals is
110 apparent, which indicates the likely wider applicability of the measurements. The endeavours
111 at the Garmisch-Partenkirchen sites deserve to be more widely known.

112

113 **Data availability**

114 The 1972-1983 Wank dataset is openly accessible through the University of Reading's
115 Research Data Archive, at <https://doi.org/10.17864/1947.000445> .

116

117

118 **Author Contributions**

119 The authors jointly drafted the manuscript.

120

121

122 **Competing interests**

123 Kristian Schlegel is an editorial board member of HGSS. There are no other competing
124 interests.
