## 16 Abstract

17

18 In Finland, auroral photography started in 1927 at the Sodankylä Geophysical  
19 Observatory (SGO) by the initiative of famous Norwegian scientist Carl Störmer. In  
20 less than two years about 600 photographs of auroras were taken at Sodankylä. Some  
21 of the images were obtained simultaneously at auxiliary stations for parallactic  
22 determinations of the height of auroral arcs. Most of the pictures of auroras were lost  
23 in the destruction of the SGO during the war in 1944. About 200 images were rescued  
24 in the archive of the Finnish Meteorological Institute where they have been recently  
25 found. These pictures of auroras are the first ones taken in Finland. These  
26 photographs are now digitized and archived in the SGO.

27 During the Polar year period 1932–1933, auroral photography was mostly  
28 discontinued but visual observations of auroras were made instead at several sites in  
29 Lapland.

30 The main sources of information about the history of auroral images are hand-  
31 written notebooks of Eyvind Sucksdorff for 1927–1929. They contain relevant data  
32 for each photograph (date, exposure time, orientation of camera etc.). In Appendix A  
33 there is a table showing the dates of rescued auroral photographs as well as the lost  
34 ones.

35 In Finland, Eyvind Sucksdorff's contribution to studies of auroras was a  
36 pioneering effort with minimal resources. Regular photographing of auroras started in  
37 Finland during the International Geophysical Year (IGY) 1957–1958.

39

## 40 1. Introduction

41

42 One of the main tasks in the auroral research in the last centuries was the  
43 determination of the height of auroral features. For achieving this goal visual  
44 observations were usually carried out at different sites using the triangulation  
45 technique (Egeland and Burke, 2013). No satisfactory results were achieved in spite  
46 of a vast number of scientific efforts. One of the most reliable height determinations  
47 was obtained by visual triangulation methods by Sophus Tromholt in Norway in the  
48 late 1870s (Moss and Stauning, 2012). Trials of height measurements and  
49 photography of auroras were made at the Sodankylä Polar year observatory 1882–  
50 1884. Photographs of auroras were unsuccessful because the sensitivity of the films  
51 available was too low for exposing faint auroral lights. The results of simultaneous  
52 visual triangular height measurements of auroras were unrealistic and scattering  
53 widely because the baseline was too short (4 kilometres) for accurate determinations  
54 of auroral forms observed at both ends of the baseline.

55 Professor Selim Lemstöm (1838–1904) (University of Helsinki) published  
56 descriptions of several auroral and telluric current experiments carried out at the  
57 Sodankylä observatory during the first Polar year 1882–1884 (Lemström, 1883, 1885;  
58 Simojoki, 1978).

59 First successful photographs of auroras were taken in the 1890s in Norway  
60 (Egeland and Burke, 2013). This technique opened a new and quantitative way for  
61 more exact determinations of the heights of auroral displays.

62 The Norwegian team of scientists lead by the Professor Carl Störmer (1874–  
63 1957) maintained in Norway in the 1910s a network of special designed auroral  
64 cameras. The cameras were installed for parallactic positions at two distant sites  
65 connected with telephone lines. The distance between the sites was typically 20–70  
66 kilometres. In this setting, the observers could direct their cameras towards the same  
67 region of sky and expose at the same time. The location of stars on the photographs  
68 fixed the astronomical orientation of auroral forms (Chapman and Bartels, 1940;  
69 Störmer, 1930, 1955; Egeland and Burke, 2013).

70 After analysing thousands of simultaneous photographs Störmer was capable to make  
71 the conclusion that the lower border of auroral forms is located about 100 kilometres  
72 above the Earth's surface. Using these parallactic auroral photographs it was possible  
73 to determine the heights of individual auroral features, but also their locations and

74 orientations in time and space (Chapman and Bartels, 1940; Egeland and Burke,  
75 2013).

76 The Sodankylä Geophysical Observatory (SGO) (Lat 67.35 °N; Lon 26.55  
77 °E) was founded in 1913 by the Finnish Academy of Sciences and it was at that time  
78 the only magnetic observatory inside the Arctic Circle and thus a suitable place for  
79 observations of polar auroras. In the early years of operations, the main tasks of the  
80 Sodankylä Geophysical Observatory were continuous magnetic recordings, regional  
81 magnetic surveys in Lapland, auroral observations as well as daily meteorological  
82 readings for the Finnish Meteorological Institute in Helsinki. The permanent staff of  
83 the observatory consisted of three employees. Eyvind Sucksdorff (1899–1955) was  
84 appointed in 1927 as the director of the Sodankylä observatory (Sucksdorff, 1952).

85 This paper gives a short description of the auroral photography and related  
86 observations carried out in the SGO in the 1920s and 1930s. Some of the first auroral  
87 photographs are presented as examples of early space weather work.

88

## 89 2. First auroral photographs at Sodankylä

90

91 There was a plan promoted by the scientific community in Norway that the auroral  
92 photography network will be expanded outside Norway for the coming Polar Year  
93 1932–1933. Carl Störmer visited Sodankylä magnetic observatory in September 1927.  
94 He proposed to Eyvind Sucksdorff, who was a skilled photographer and astronomer,  
95 that parallactic auroral photographs should be started in North Finland for extending  
96 the auroral photograph network in Norway in cooperation between Finnish and  
97 Norwegian scientists for the International Polar year programme. As planned by  
98 Störmer, photography of auroras started in Sodankylä and in a nearby station in  
99 November 1927.

100 Störmer's auroral camera consisted of a glass plate (10 x 14 cm) coated with  
101 photographic emulsion. The lens of the camera was manually movable in such a  
102 manner that six individual photographs could be taken on the same plate. The  
103 Norwegian auroral cameras were not suitable for taking all-sky pictures because the  
104 field of view was typically limited to about 25 x 25 degrees on the sky. The exposure  
105 time was selected according to the brightness of auroras visible on the sky. Usually  
106 the time was 1–30 seconds.

107 During less than two years in 1927–1929 Eyvind Sucksdorff and his assistants  
 108 took about 600 photographs of auroras at the SGO using cameras designed by the  
 109 Störmer's scientific team. A few photos were taken at the auxiliary stations. The major  
 110 part of these photos were lost during the war 1944 when German military troops  
 111 destroyed totally all the buildings and archive of the Sodankylä Geophysical  
 112 Observatory (Sucksdorff et al. 2001; Böisinger, 2021). However, paper copies of about  
 113 200 photographs were archived before the war in the library of the Finnish  
 114 Meteorological Institute in Helsinki. Recently, this historical material was found, and  
 115 the present presentation is based on this collection of pictures of auroras.

116 First parallactic auroral photographs were taken simultaneously at the  
 117 Sodankylä observatory and at the auxiliary station Kelujärvi some 20 kilometres to  
 118 the north from the observatory. Both sites were connected with a telephone line for  
 119 simultaneous communications during the operations with cameras. Up to the end of  
 120 1927 more than 100 auroral pictures were taken at the Sodankylä observatory alone.

121 Fig. 1 shows the Norwegian aurora camera on the top of the main building of  
 122 the Sodankylä Geophysical Observatory in the early 1930s.

123  
 124 Figure 1. Annikki Sucksdorff (1904–1986) was the assistant of the Sodankylä  
 125 Geophysical Observatory 1927–1945 (Sucksdorff, 1952). In the photograph she is  
 126 working with auroral observations on the roof of the observatory building. An  
 127 Störmer camera is in the front of her. The river Kitinen can be seen in the background.  
 128 (Photo: Finnish Meteorological Institute).

129

130 The first simultaneous photographs at Sodankylä and Kelujärvi sites were  
 131 taken in January 1928. During one night more than 20 successful exposures were  
 132 captured on films. They were sent to Störmer's laboratory in the Oslo University for  
 133 determinations of auroral heights using a specially constructed projector for the

134 photographs. Such a device was not in use in Sodankylä. Unfortunately, no  
135 information exists about the results of the height analysis in Oslo.

136 In the winter of 1927–1928 there were nine nights suitable for  
137 photographing at the Sodankylä observatory, and almost 200 auroral photographs  
138 were taken. In the winter of 1928–1929 the number of auroral pictures collected was  
139 almost 400 (a list of dates, see Appendix A). Later in the 1930s auroral photography  
140 was only a minor part in the work at the Sodankylä observatory and very few pictures  
141 were taken.

142 The auroral images available have been digitized. They can be found in the  
143 digital archive of the SGO together with the supporting metadata information. The  
144 URL address is  
145 [https://sgo.fi/Data/Optical/SGOHistAurObs/Sucksdorff1927\\_1929/index.php](https://sgo.fi/Data/Optical/SGOHistAurObs/Sucksdorff1927_1929/index.php).

146 Figs. 2 and 3 show examples of historical images of auroras at Sodankylä  
147 taken in March 1928. They belong to the first photographs of auroras in Finland. Fig.  
148 4 depicts simultaneous auroral arcs at Sodankylä observatory and at the auxiliary site  
149 Kelujärvi some 20 kilometres north from Sodankylä.

150  
151

152  
153

154 Figure 2. An auroral arc photographed at Sodankylä observatory on March 13, 1928  
155 20:32 UT. Faint spots on left upper corner belong to the star cluster Pleiades in the  
156 constellation of Taurus. The exposure time was 39 seconds. The centre of the photo is

157 towards the west and about  $30^\circ$  from the horizon. (Photo: E. Sucksdorff's collection  
158 SGO).

159

160 Figure 3. An auroral arc at the Sodankylä observatory on March 13, 1928 20:13 UT.  
161 The bright star on the centre is Arcturus in the constellation of Boötes. The exposure  
162 time was 9 seconds. The centre of the photo is towards the east and about 20 degrees  
163 from the horizon (Photo: E. Sucksdorff's collection SGO).

164

165

166

167

168 Figure 4. Left: Auroral arc at Sodankylä on January 27, 1928 19:25 UT.  
169 Right: The same at the auxiliary Station Kelujärvi at a distance of 20 kilometres from  
170 Sodankylä. The exposure time was 25 seconds. The lower edge of the auroral form is  
171 about 20 degrees above the horizon towards the brightest stars of the constellation

172 Pegasus in the west. One such star ( $\alpha$  Pegasi) can be seen in the right lower corner in  
173 both images. (Photo: E. Sucksdorff's collection SGO).

174

### 175 3. Great magnetic storm, February 27, 1929

176

177 The period 1927–1929 during which photographs of auroras were taken at the  
178 Sodankylä observatory coincided with the maximum phase of the sunspot cycle 16.  
179 The February 27, 1929 magnetic storm observed at the SGO and other magnetic  
180 stations at high latitudes was one of the major magnetic storms during the solar cycle  
181 16 (1923–1933) (e.g., Goldie, 1929; Rowland, 1929, Newton, 1930). According to the  
182 visual observations made by E. Sucksdorff, this storm started around 17:30 UT with a  
183 magnificent discrete auroral display (so called corona) at the zenith covering the sky  
184 from east to west. A new corona appeared at midnight illuminating the snow-covered  
185 landscape. First magnetic signals of the storm occurred one day earlier on February 26  
186 around midnight (Fig. 5). During the most intensive period of the storm around  
187 midnight February 27–28, the magnetic three-hour  $K$ -index increased up to 8/9 ( $K = 8$   
188 corresponds to amplitudes  $990 \text{ nT} < \Delta H < 1500 \text{ nT}$  and  $\Delta H > 1500 \text{ nT}$  when  $K = 9$ )  
189 as derived from the Sodankylä magnetic records. The greatest deviation in the hourly  
190 means of the magnetic north component ( $X$ ) was about 1 000 nT in the late evening  
191 on February 27 (Fig. 5).

Figure 5. Three component (X, Y, Z) hourly magnetic variations as reproduced from the magnetic recordings of the Sodankylä Geophysical Observatory from February 26–28, 1929. The daily local activity index ( $A_k$ ) for February 29 was 79. The main phase of the magnetic auroral storm occurred around midnight on February 27–28. The first signals of the storm appeared in late evening on February 26th. Hourly values are from the SGO magnetometer data archive.

207

208

209 Figure 6. Auroral displays on February 27, 1929 as captured by a camera at the  
 210 Sodankylä Geophysical Observatory. The times (hh:mm:ss in UT) for the six  
 211 photographs and the exposure times (in brackets) are as follows:

212

213 1st row from left to right: 18:28:01 (16), 18:28:39 (8)

214 2nd row: 18:28:57 (11), 18:29:38 (11)

215 3rd row: 18:31:04 (9), 18:32:40 (12)

216

217 The two top pictures show auroral lights reflected from the frozen river Kitinen. The  
 218 black belt under the auroral lights, which is the tree line on the other side of the river,  
 219 is seen in all pictures, most clearly in the top row. Next four pictures show rapidly  
 220 changing auroral forms, veils and spirals. Two bright spots are planets Jupiter (upper)  
 221 and Venus (lower) on the west and about 15° from the horizon. (Photo: E.  
 222 Sucksdorff's collection SGO).

223

224 Fig 6. Shows an example of temporal changes of the auroral storm of  
 225 February 27 as recorded by the auroral camera in a short time interval of about 5  
 226 minutes. There are six single pictures captured on the same glass plate taken in about  
 227 30 seconds intervals. In the figure one can see bright veils and patches of auroras as  
 228 well as spiral shapes. On the background of auroral lights there are two bright planets,  
 229 Venus and Jupiter.

230 In addition to the photographs in Fig. 6, there are available two more plates  
231 both including six single images of auroras starting at 18:22 and 20:23 UT. The  
232 remaining 147 auroral photographs, taken during the February 27 storm (17–24 UT),  
233 were lost in the destruction of the SGO during the war in 1944 (see, Appendix A).

234 Carl Störmer and his colleagues were able to take simultaneous photographs  
235 of auroras at two sites near Oslo (Norway) during the nights in February 26–28, 1929.  
236 The amount of usable photographs obtained was over 100. A sample of images was  
237 published together with height analysis of auroral forms (Störmer, 1930; Chapman  
238 and Bartels, 1940, Vol. I, p. 462). Based on calculations from two simultaneous  
239 images from early morning hours on February 27, the height of the lowest border of  
240 auroras was located at an altitude of 82 kilometres.

241 The February 27, 1929 storm was reported in many contemporary  
242 newspapers in Finland and in international scientific studies (e.g., Goldie, 1929;  
243 Rowland, 1929; Ulrich, 1929; Newton, 1930; Chapman and Bartels, 1940; Störmer,  
244 1930, 1955).

245

#### 246 4. Visual observations of auroras during the polar year 1932–1933

247

248 For the International polar year 1932–1933 the scientific programme of the Sodankylä  
249 Geophysical Observatory was extended by new observations such as earth currents,  
250 atmospheric electricity and magnetic pulsations (Sucksdorff, 1952; Bössinger, 2021).  
251 SGO was equipped by modern magnetic registration devices provided by the Danish  
252 Meteorological Institute and designed by Dan Barfod la Cour who was the President  
253 of the Polar year programme and the director of the Danish Meteorological Institute.  
254 By his initiative Sodankylä observatory was selected as a training place for the  
255 scientists involved with magnetic measurements in the Arctic.

256 Two temporary observatories during the Polar Year 1932–1933 were set up  
257 in Finland. They were Petsamo (69.5°N; 31.2°E) near the coast of the Arctic Sea, now  
258 in the territory of Russia, and Kajaani in East-Finland (64.2°N; 27.7°E) (Tommila,  
259 1937; Sucksdorff et al., 2001).

260 Systematic observations of auroras by means of visual sightings were also  
261 included in the programme. One goal of this work was to achieve a more accurate  
262 description of the occurrence of auroras and magnetic variations both in time and  
263 space around Earth's arctic area.

264 E. Sucksdorff introduced special graphical symbols for different types of  
265 auroras for the Polar Year plan of visual observations. About 20 different symbols  
266 indicated various manifestations of auroral shapes, colours and their occurrence times.  
267 Sucksdorff made visual observation of auroras during the Polar year 1932–1933 that  
268 were continued observations up to 1944 at the Sodankylä Geophysical Observatory.  
269 The material accumulated contains coded information of auroral appearances from  
270 about 750 nights. The original hand-written data is stored in the archive of the SGO.  
271

272

273 Figure 7. Eyvind Sucksdorff demonstrates a device (quadrant) for visual  
274 determinations of the height of auroral arcs. It consists of a thin wooden plate with a  
275 scale and a plumb line suspended to the plate showing the elevation angle of auroral  
276 arcs visible. The observer turns the quadrant until the upper edge of the plate points to  
277 the arc of an auroral display. (Photo: Finnish Meteorological Institute).  
278

279 Because the results of the simultaneous photography of auroral arcs during  
280 1927–1929 were not very successful, Sucksdorff developed a simple visual method  
281 instead. He constructed a special aiming device, called a quadrant, by which the  
282 height of well defined and stable auroral arcs could be determined visually (Fig. 7).  
283 The height of arcs, as measured in elevation angles from the horizon, was read from a  
284 scale attached on the quadrant. Sucksdorff organized coordinated campaigns in  
285 Lapland in which 12 volunteer observers, like schoolteachers, made sightings with the  
286 quadrant at different places. If two or more observers have measured the same arc at

287 the same time, its true height could be determined. Although it was known already in  
288 the 1910s that the average height of lower edge of auroral forms is about 100  
289 kilometres, it was not clear how low the aurora lights could occur in extreme auroral  
290 cases (Störmer, 1930; Chapman, 1932). One of goals in Sucksdorff's campaign was  
291 search of these supposed low altitude auroras.

292 Visual observations were made during the Polar year period and continued  
293 at some places up to 1936. At an auxiliary station scientists from the Danish  
294 Meteorological Institute made continuous observations of auroras up to 1936 as  
295 planned by Sucksdorff, and maintained magnetic recordings. However, the result of  
296 several years of measurements was that only little relevant information about the  
297 appearance of simultaneous auroral arcs was revealed in the observations for accurate  
298 calculations of the location and height of auroral arcs. The observations collected  
299 have not been analyzed but the whole material is now in the archive of the SGO.

300 Visual observations of the occurrence of auroras were made in connection  
301 with daily meteorological observations at Sodankylä since the founding of the  
302 observatory in 1914. Such routine observations were continued until 1954 when  
303 auroral observations were removed from the daily meteorological readings. The 40  
304 years period of visual observations of auroras provide some information for long-term  
305 variations in the occurrence rate of auroras. There were more than 1800 nights with  
306 auroras during 1914–1954 in Sodankylä (see, Appendix B). Fig. 8 shows the annual  
307 number of nights illuminated by auroras during clear sky conditions at Sodankylä.  
308 Also shown are annual sunspot numbers and local magnetic activity ( $Ak$ ). In Fig. 8  
309 the annual occurrence rate of auroras at Sodankylä are compared with annual number  
310 of low-latitude (geomagnetic latitude  $< 57$  deg) auroras obtained from a compilation  
311 by Legrand and Simon (1987). One can see that the annual numbers of auroral nights,  
312 from local and low-latitude observations, follow the magnetic activity and varying  
313 sunspot numbers in the course of 11-year sunspot cycle moderately well. The changes  
314 from year to year seem to vary in such a way that the largest amount of auroral nights  
315 are seen during the declining solar cycle phase. However, there are certain anomalies  
316 in the auroral variation at the SGO compared with magnetic activity and low-latitude  
317 auroral occurrences. This is probably due to varying weather and cloudy conditions  
318 but certain non-geophysical factors have also contributed to the inhomogeneity of the  
319 results based on visual auroral observations (Lockwood et al., 2018). Correlation

320 between annual auroral occurrence rate at the SGO and local magnetic activity is  
 321 rather low, 0.51.

322 Tanskanen et al. (2005) and Tanskanen (2009) found that the largest  
 323 substorm numbers and peak amplitudes were found during the declining solar cycle  
 324 phases. This is similar to conclusion here that auroral occurrence rate is generally  
 325 enhanced during the declining phase of a solar cycle. In addition there seem to be an  
 326 increasing multi-decadal trend in the annual number of auroral nights connected with  
 327 similar increasing tendency in the long-term magnetic activity and the peak numbers  
 328 of sunspots ultimately associated with solar processes and interplanetary magnetic  
 329 field (e.g., Mayaud, 1972; Lockwood, 2001). The long-term trend in the annual  
 330 auroral occurrence rates shown in Fig. 8 may be connected with the centennial  
 331 Gleissberg cycle of solar activity (e.g., Feynman and Ruzmaikin, 2014; Le Mouél et  
 332 al., 2017).

333

334 Figure 8. Red: Time variations in the number of auroral nights obtained by visual  
 335 observations of auroras at Sodankylä 1914–1954 (Data: Meteorological yearbooks -  
 336 Finnish Meteorological Institute).

337 Blue: Annual number of visual auroras at subauroral latitudes (Data: Legrand and  
 338 Simon (1987).

339 Dotted black: Annual means of local magnetic activity index  $Ak$  (multiplied by a  
 340 factor 3) ( Data: Magnetic yearbooks - Sodankylä Geophysical Observatory).

341 Histograms: Annual sunspot numbers (Data: Solar Influences Data Analysis Center  
 342 WDC-SILSO).

343 Numerical values of the data shown in Fig. 8 are given in Appendix B.

## 344 5. Discussion

345

346 Although no significant scientific results were obtained from the aurora images taken  
347 at the Sodankylä Geophysical Observatory in 1927–1929, the cooperation with  
348 leading Norwegian scientists yielded a new area for the observatory's operations and  
349 contacts with the scientific community outside Finland. Photographs of auroras  
350 obtained almost one hundred years ago are the first ones in Finland. The entire  
351 observational material, except to that lost during the war in 1944, collected in 1920s  
352 and 1930s can be found in an open access at the SGO.

353 The dates of auroral photography are given in Appendix A.

354 In Finland, Sucksdorff was quite alone in auroral studies in 1920s and  
355 1930s. He had to work with very limited resources but the results were important for  
356 the future auroral work in Finland. The situation was totally different in Norway  
357 where several outstanding scientists with high reputation in the scientific community,  
358 such as Kristian Birkeland, Carl Störmer, Ole Krogness, Lars Vegard, Leiv Harang  
359 and many others, were involved with observations and scientific studies of aurora and  
360 related cosmic phenomena. Space physics was in the teaching program in several  
361 Norwegian universities and institutions since the 1910s. In Finland, there was no  
362 academic teaching or research at all in these fields before the 1950s.

363 Regular auroral photography was restarted during the IGY (International  
364 Geophysical Year) 1957–1958 when a modern Stoffregen-type all-sky camera,  
365 constructed in the Finnish Meteorological Institute by Eyvind Sucksdorff's son  
366 Christian (1928–2016), was set up at the Sodankylä Geophysical Observatory  
367 (Nevanlinna and Pulkkinen, 2001; Schlegel and Lühr, 2014; Böisinger, 2021).
